Introduction to Graph Theory

Ioannis Chatzigiannakis

Sapienza University of Rome

Lecture 17

Graph Definition

- ▶ We denote a graph by $G = G(V, E)$, where
 - ▶ V represents the set of vertices
 $V = \{a, b, c, d, e\}$
 - ▶ E represents the set of edges
 $E = \{(a, b), (a, c), (b, c), (b, d), (c, d), (c, e)\}$

Basic Definitions

- ▶ We denote $|V| = n$ – the number of vertices.
- ▶ We denote $|E| = m$ – the number of edges.
- ▶ Two vertices u, v are called **adjacent** or **neighboring** vertices if there exists an edge $e = (u, v)$.
- ▶ We say that edge e is **incident** to vertices u and v .
- ▶ We say that vertices u and v are **incident** to edge e .
- ▶ A **loop** is an edge from a node to itself: (u, u) .

Degree of the Vertex

- ▶ The number of edges incident to a given vertex v is called **the degree of the vertex** and is denoted $d(v)$.
- ▶ For every graph $G = G(V, E)$,

$$\sum_{u \in V} d(u) = 2 \cdot |m|$$

- ▶ Notice that an edge connecting vertices v and w is counted in the sum twice: first in the term $d(v)$ and again in the term $d(w)$.

Subgraphs

- ▶ A **subgraph** G' of G consists of a subset of V and E . That is, $G' = (V', E')$ where $V' \subset V$ and $E' \subset E$.
- ▶ A **spanning subgraph** contains all the nodes of the original graph.

Paths

- ▶ A **path** is a sequence of vertices and edges of a graph – Vertices cannot be repeated. Edges cannot be repeated.
- ▶ A path of length k is a sequence of vertices (v_0, v_1, \dots, v_k) , where we have $(v_i, v_{i+1}) \in E$.
- ▶ If $v_i \neq v_j$ for all $0 \leq i < j \leq k$ we call the **path simple**.
- ▶ If $v_0 = v_k$ for all $0 \leq i < j \leq k$ and $v_0 = v_k$ the **path is a cycle**.
- ▶ A path from vertex u to vertex v is a path (v_0, v_1, \dots, v_k) such that $v_0 = u$ and $v_k = v$.

Shortest Paths

- ▶ A **shortest path** between vertices u and v is a path from u to v of minimum length.
- ▶ The distance $d(u, v)$ between vertices u and v is the length of a shortest path between u and v .
- ▶ If u and v are in different connected component then $d(u, v) = \infty$.

Graph Diameter

- ▶ The diameter D of a connected graph is the maximum (over all pairs of vertices in the graph) distance.

$$D = \max_{(u,v): u,v \text{ connected}} d(u, v)$$

- ▶ If a graph is disconnected then we define the diameter to be the maximum of the diameters of the connected components.

Breadth-first Search

- ▶ Given a graph $G(V, E)$,
- ▶ and a distinguished **source** vertex u ,
- ▶ breadth-first search systematically explores the edges of G to “discover” every vertex that is reachable from u .
- ▶ It computes the distance from u to each reachable vertex.
- ▶ It computes a spanning subgraph of G , the “breadth-first tree”, with root u that contains all reachable vertices.
- ▶ For any vertex v reachable from u , the path in the breadth-first tree from u to v corresponds to a “shortest path” from u to v in G .

Example of Execution of Breadth-First Search Algorithm

Initial Graph

The graph contains 9 vertices, 14 edges

Vertex **1** is the **source** node.

Vertex **1** is **discovered**.

Vertices **2,5** are the **frontier**.

All other vertices are not discovered.

Example of Execution of Breadth-First Search Algorithm

1st Round

Vertex **1** sends **examines** adjacent vertices.

Vertex **2,5** are **discovered**.

Vertices **3,4,7,8,9** are the **frontier**.

Example of Execution of Breadth-First Search Algorithm

2nd Round

Vertices **3,4,7,8,9** are the **discovered**.

Vertex **6** is the **frontier**.

Example of Execution of Breadth-First Search Algorithm

3rd Round

All vertices are discovered.

Example of Execution of Breadth-First Search Algorithm

Final Graph

Breadth-first search tree constructed.

Bridges of Königsberg

Euler was interested in whether he could arrange a tour of the city in such a way that the tour visits each bridge exactly once

Bridge Problem

Find a tour through a city (located on n islands connected by m bridges) that starts on one of the islands, visits every bridge exactly once, and returns to the originating island.

Input: A map of the city with n islands and m bridges.

Output: A tour through the city that visits every bridge exactly once and returns to the starting island.

Transformation of the Map into a Graph

- ▶ Every island corresponds to a vertex.
- ▶ Every bridge corresponds to an edge.

Eulerian Cycle Problem

Find a cycle in a graph that visits every edge exactly once.

Input: A graph G .

Output: A cycle in G that visits every edge exactly once.

Hamilton's Game

- ▶ Sir William Hamilton invented a game corresponding to a graph whose twenty vertices were labeled with the names of twenty famous cities.
- ▶ The goal is to visit all twenty cities in such a way that every city is visited exactly once before returning back to the city where the tour started.

Hamiltonian Cycle Problem

Find a cycle in a graph that visits every vertex exactly once.

Input: A graph G .

Output: A cycle in G that visits every vertex exactly once.
